AURUM Whitepaper

AURUM

1. Introduction

AURUM is a Bitcoin-secured token system that begins on Ethereum and evolves into its own blockchain.

2. Philosophy

AURUM locks real Bitcoin in a public, untouchable reserve. Transparent, irreversible, and community-driven.

3. Ethereum Phase

The AU token is sold for USDC. Most of the raised funds are converted into BTC and placed in a visible reserve.

4. The Reserve

BTC is locked forever and publicly viewable. AU has a real BTC-backed floor - but no upper limit.

5. Redemption

AU can be redeemed for aBTC (wrapped BTC inside the AURUM system) with a 21% penalty. Redeemed AU is burned.

6. AURUM Chain

A future blockchain will distribute AU via staking. Daily emission: 450 AU. Halving aligned with Bitcoin.

7. Tokenomics

 Total Supply: 21 million AU

 Public Presale only in USDC

 No team allocation or insider deals

 BTC reserve grows with each sale

 Deflation via AU burns during transfers

8. Proof of Value

Live BTC reserve display. Immutable and transparent for all.

9. Vision

AURUM acts before institutions absorb all available BTC. Its a long-term system to secure digital scarcity.

10. Open Source

The code will be public. No central control. The community shapes the future.
